

Assessing agricultural drought severity is critical for food security. Remote sensing data, particularly the Vegetation Condition Index (VCI) from MODIS product¹, helps evaluate drought extent. Monthly VCI maps from January to April are merged to create a comprehensive growing season map, categorized into five drought severity classes. This map is then visualized using a hexagon grid with cells of approximately 350 square kilometers. The 2021 drought severity assessment reveals that numerous provinces in Afghanistan experienced higher levels of drought, especially in the extreme and severe classes. These findings are important for the Afghanistan Emergency Food Security Project (OSRO/AFG/213/WBK), providing essential information to address food security challenges and implement appropriate interventions.

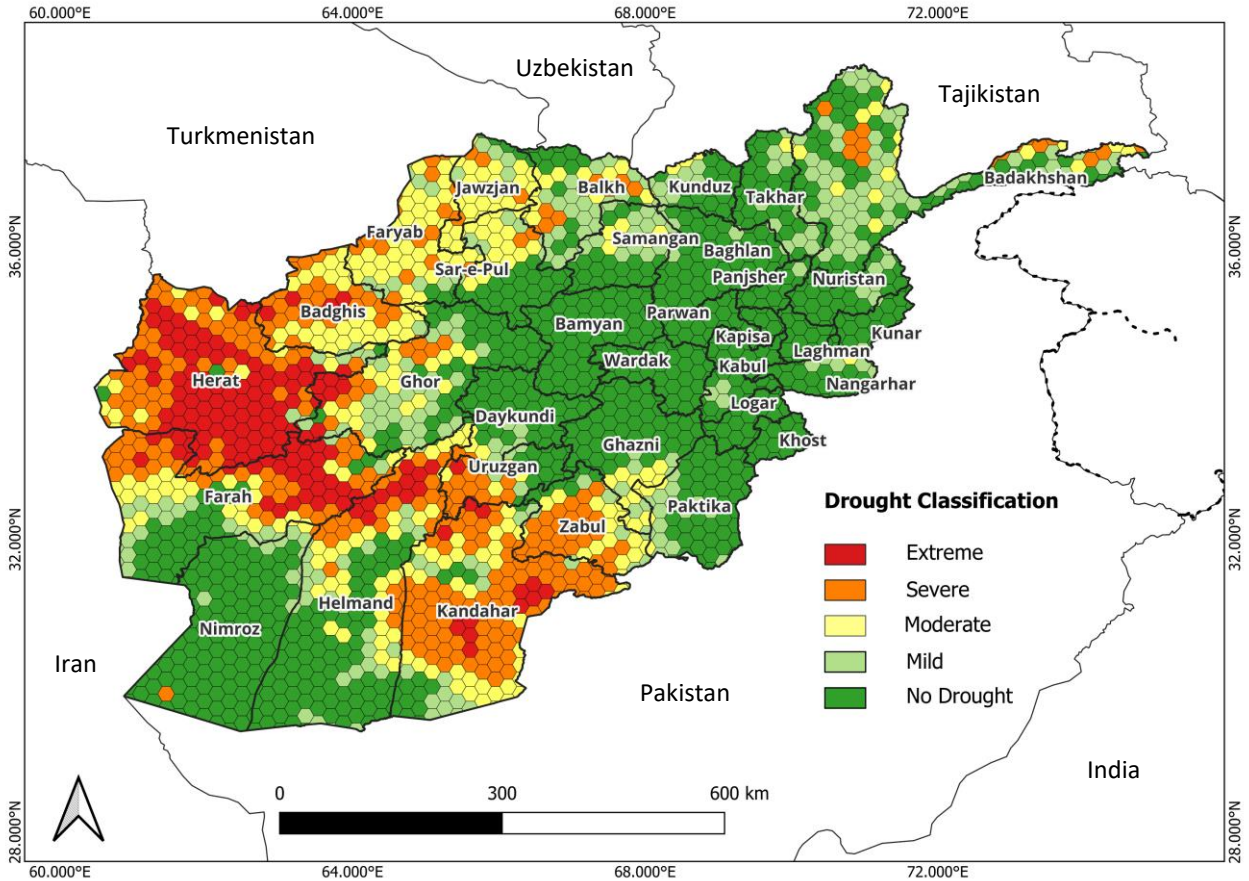

Figure 1: Spatial distribution of drought classification in 2021 in Afghanistan.²

Key Finding:

The results indicate that significant drought conditions were observed across various regions, including western, northern, and southern. These conditions were classified into five classes, including extreme (11 percent), severe (17 percent), moderate (15 percent), mild (13 percent), and no drought (44 percent). Table 1 shows the provinces that were most affected by extreme and severe drought.

Table 1: Example of five top most provinces affected by extreme and severe drought (percentage of the province and extent in km²) in 2021.

Province	Extreme		Province	Severe	
	km ²	(%)		km ²	(%)
Herat	34 197	40	Kandahar	25 680	20
Farah	14 574	17	Herat	17 623	14
Kandahar	9 044	11	Farah	12 795	10
Helmand	5 826	7	Badghis	10 144	8
Ghor	4 826	6	Helmand	9 848	8
